

PRESIDENT'S REPORT 2021

Activities (that I am aware of) in 2021 are (in order of posts on the ORSNZ website):

- 1) After 5's with Vaughan Grant – Designing supply chain networks
- 2) IFORS Global Webinar 5 Feb 2021
- 3) WiDS Worldwide Conference
- 4) IFORS Global Webinar 29 Mar 2021
- 5) ORAHS (Operational Research Applied to Health Services) 2021
- 6) Upcoming abstract deadlines for IFORS and INFORMS conferences
- 7) IFORS Global Webinar: Gender Diversity in the World, June 29
- 8) The importance of complexity modelling during and after the COVID-19 pandemic: Joint ORSNZ-TPM seminar at University of Canterbury
- 9) IFORS Webinar @ Sep 20: Excellence in Operations Research Showcase
- 10) IFORS Webinar @ Nov 17: Global Sports Analytics

No conference in 2021 a conference was nominally planned for 25-26 November 2021, but was cancelled due to the pandemic.

ORSNZ website and "What is the point of ORSNZ?" ORSNZ undertook a strategic planning activity which resulted in a strategic direction slide deck and a website design (attached). The main "drive" is to make the website a hub for activity given the move to online activity forced by the pandemic.

Roles and responsibilities I have been in the process of reviewing these for over a year, but time constraints means this is still work-in-progress... I think having clear guidelines for people taking up new roles is important (and even people continuing in roles).

Succession planning I have been president since 2017 and Tony has been an amazing secretary for the whole time. I am happy to stay on or step down, but I think we need some new energy in the leadership. I am fulfilling roles as a NZ rep on the Global Partnership for AI (GPAI) and Deputy Director for Te Pūnaha Matatini so my time is very stretched. This would suit an early- to mid-career person.

In Memoriam "Peter Whittle, who died on 10 August 2021, at 94 years of age, will be remembered as a pioneer across the fields of probability, statistics and optimization." Full tribute attached.

Finally, I hope everyone is staying well and that the effect of the pandemic will abate soon. Let's hope for a conference in 2021!

Memorial Tribute

PETER WHITTLE, 1927-2021

By Frank Kelly

(Peter Whittle in 1985, by Peter Lofts)

Peter Whittle, who died on 10 August 2021, at 94 years of age, will be remembered as a pioneer across the fields of probability, statistics and optimization. He wrote a number of important papers, but it is in his books that one can best appreciate the broad sweep of his achievements and the simplicity, unity and generality of his approach. His twelve major volumes covered times series, prediction, constrained optimization, dynamic programming, optimal control, stochastic systems, the foundations of probability theory and neural nets. Several of these works were ahead of their time: indeed some of his early works appear to have been written for the audience of today, such is the extent to which they anticipated subsequent developments.

Peter Whittle was born in Wellington, New Zealand, on 27 February 1927. His parents (Percy Whittle and Elsie Tregurtha) were both New Zealanders, of 19th century British and Irish

extraction. His father, an orphan, joined the Post Office in 1914 and rose to become Assistant Postmaster for Wellington; and his mother was a schoolteacher. Peter spent his first 22 years in the spectacularly beautiful Island Bay, south of Wellington, facing onto Cook Strait. He graduated from the University of New Zealand with a B.Sc. in mathematics and physics in 1947, first across NZ in the exams for these subjects, and a M.Sc. in mathematics in 1948. He intended a career in mathematical physics, but vacation work in the NZ Department of Scientific and Industrial Research (DSIR) offered statistical problems from agriculture and biometrics that attracted his scientific interest, and his first paper was on the design of experiments.

A travelling scholarship in 1949 took Peter to Uppsala, Sweden, for his doctoral work under Hermann Wold. A profound influence on Whittle was Maurice Bartlett, then working in Manchester. He began his work on time series analysis, and in his doctoral thesis and four papers following on from it he essentially solved the large-sample inference problem for a stationary time series generated by a linear Gaussian model. The terms “multivariate Whittle likelihood” and “Whittle estimation” are now common, but this early groundbreaking work was not at the time widely appreciated: Whittle remarked that, perhaps in unconscious emulation of the admired Bartlett, he wrote too gnomically. In marked contrast his corresponding analysis for spatial processes, published in 1954, had an immediate and sustained impact. His asymptotic inference theory for Gaussian processes and related spatial processes was ahead of its time in considering power law covariance functions, now central in image analysis.

After Uppsala, Peter returned in 1953 to New Zealand and the DSIR. The subsequent six years were to be deeply formative. Work on New Zealand rabbits (pests of the first order) produced the Whittle threshold theorem for stochastic process models of an epidemic. Oscillations in oceanographic data (from the Island Bay rock channels) uncovered non-linear effects. His time-series work led into the study and statistical analysis of spatial models. He was able to show for Fairfield Smith’s collection of uniformity trial data the spatial autocorrelation functions behaved as inverse powers in their tails and that s^{-1} behaviour occurred dominantly. He showed that a spatio-temporal model explained the s^{-1} law; fractals and self-similar processes were as yet unthought of. During this period he also became interested in polymerisation and in reversibility, both topics he would return to later. Peter believed that his subsequent interests and career were largely shaped by his time in the NZ Department of Scientific and Industrial Research, working on problems from geophysics, agriculture and industry. His superior there later wrote “His genuine interest in people and their work, his boyish sense of humour and lack of pretension, made it possible for him to carry his own intellectual pre-eminence without exciting jealousy or antagonism.”

Peter came back to Britain in 1959 as a lecturer in the Statistical Laboratory, Cambridge. In 1961 he moved to the Chair of Mathematical Statistics at Manchester, succeeding Maurice Bartlett. Peter's interest in optimization developed at Manchester; he kept his interest in spatial processes, with his student David Brook producing an early result on Markov random fields; and he obtained his first results on networks of queues and partial balance.

In 1967 Peter returned to Cambridge as the Churchill Professor of Mathematics for Operational Research, a newly established chair endowed by Esso. The position gave Peter the perfect platform for his vision that what needed developing was not just narrow sense operational research, but the whole area of what in Cambridge is now termed applicable mathematics. This includes, for example, probability, statistics, optimization, game theory and those aspects of disciplines such as control theory, communications theory and mathematical economics which might be pursued by someone technically based in probability and optimization. Developments in the US had convinced Peter of not only the practical importance of these topics but also the depth and coherence of the theory they generate. He felt that the subject of statistics itself is thoroughly penetrated by optimization concepts and is only viewed aright when embedded in this larger context (a view now taken for granted in statistics generally and in areas such as machine learning). Peter set about the task of creating the new courses to deliver this vision, and this began an evolution of the Mathematical Tripos at Cambridge that has continued to this day. He served as Director of the Cambridge Statistical Laboratory from 1973-1986.

By the time of Peter's second major work on time series (*Prediction and Regulation*, 1963, revised second edition in 1983) his interest had moved from inference to prediction and control. His four volumes on optimization marked his continuing interest in stochastic control, and in temporal optimization generally, using dynamic programming ideas. *Optimization under Constraints* (1971) is shot through with insight in a prose style combining power and economy. Notable in *Optimization over Time* (1983) is Peter's treatment of the multi-armed bandit problem. Despite its whimsical name this problem – the sequential allocation of effort in the presence of uncertainty – arises in areas as varied as the design of clinical trials or the choice of exploration avenues in artificial intelligence. The problem was first formulated during World War II and, as Peter famously remarked, efforts to solve it so sapped the energies of Allied analysts that the suggestion was made that the problem be dropped over Germany, as the ultimate instrument of intellectual sabotage. Later, in *Risk-Sensitive Optimal Control* (1991) the very complete theory for the linear/quadratic/Gaussian case is transferred to a significantly more general case.

His vision for the whole area of applicable mathematics was by now well established, providing the mathematical foundations for central areas of engineering and economics. Mathematicians often do not see the impact of their work on other fields. It is noteworthy that in the Foreword to the second edition of *Prediction and Regulation*, Thomas Sargent, later awarded the Nobel Prize in Economics for empirical research on cause and effect in the macroeconomy, writes on the importance of Peter's work for understanding dynamic economic phenomena.

His book *Probability via Expectation* (1970, expanded in 2000) is an exposition of probability theory which formulates its axioms in terms of expectation rather than measure, developing Peter's view that this approach has advantages at many levels. One advantage is that probability theory and probability of quantum theory are seen to differ in only a modification of the axioms – a modification rich in consequences, but (as in so much of Peter's work) succinctly expressible.

Peter had a life-long interest in statistical/physical models, and the book *Systems in Stochastic Equilibrium* (1986) collects as one of its parts Peter's work on polymerization and random graphs, and also his work on partial balance in networks. His work on networks continued with *Neural Nets and Chaotic Carriers* (1998) and *Networks: Optimization and Evolution* (2007). In his final years he maintained his interest in neural nets, finding the notions of self-optimizing and self-organizing systems both fascinating and of enormous potential. But even he might have been surprised to see the pace of the ongoing realignment of mathematics, with statistics, optimization and machine learning permeating applied mathematics and leading to remarkable advances across swathes of physical, biological and social science.

He was awarded the Research Medal of the New Zealand Association of Scientists in 1954, and an Honorary D.Sc. by the Victoria University of Wellington in 1987. His many other distinctions included the Sylvester Medal of the Royal Society, the Guy Medal in Silver and Gold of the Royal Statistical Society, and the Lanchester Prize and the John von Neumann Theory Prize of the US Institute for Operations Research and Management Science. He was a Fellow of the Royal Society and an International Member of the US National Academy of Engineering.

Peter Whittle married Käthe Blomquist in 1951, and they had six children. Käthe was Finnish and they had met in Uppsala. They did their courting in Swedish, a second language to each and their only common language. He sometimes described himself as a “loner” and as far as his academic work was concerned he was certainly refreshingly away from the crowd. But it is hard to think of anyone who took such pleasure from his large family as really alone. The keenness of Peter’s observation of personalities was another factor – to be read so clearly can be disconcerting.

At school in New Zealand Peter played the flute in the school orchestra, and he got pleasure from making and playing instruments throughout his life. He was particularly attracted to woodwind instruments, especially the oboe. In his middle years he learned the flamenco guitar, mastering the *rasgueado* – the continuous drum-roll achieved with the backs of the fingernails. He played the chanter - the part of the bagpipes that creates the melody, without the bag and drones. Languages were another interest: French, Swedish and Russian early in his life, and after retirement Scottish Gaelic whose evocative charms fascinated him. He was a talented runner and kept up distance running into his later years. He enjoyed carpentry, general DIY and toymaking, finding them a useful counterweight to his academic work. A poignant memory of a daughter is a necklace pendant with paua shell inlay. Music was all around the family, from Irish drinking songs, keening Gaelic laments, Swedish love songs and Māori hakas, to Bach concertos and Sibelius symphonies, reflecting not only the breadth of Peter’s aesthetic sense and the richness of his mind, but also the shifting aspects of his interior life and personality. The music of Ravel, particularly, with its precision, refinement and elegance, accorded well with his mathematical mind.

Peter’s wife Käthe died in 2020. He is survived by his children Martin, Lorna, Miles, Gregory, Jennifer and Elsie, seven grandchildren and one great granddaughter. Throughout his life he greatly missed New Zealand, and asked that his ashes be cast into the waters of Island Bay, Wellington, New Zealand, which he had grown up overlooking.
